

Grant Swift

Mechanical & Aerospace Engineering student, University of Oklahoma.
Seeking a summer engineering internship.

grant.swift1@yahoo.com · 949-212-2967 · linkedin.com/in/grant-swift1 · github.com/grant105-ops

I like building things. I also like trying to break them. Most of my work goes into designing systems that hold up against anything I can throw at them, then testing until something gives, and rebuilding it stronger each time.

SKILLS

CAD & Design	SolidWorks, AutoCAD
Analysis	Statics, Dynamics, Thermodynamics, Design & Manufacturing Processes
Hands-on	3D printing, machining, woodworking, test setup & measurement
Software	JavaScript, Node.js, Express, React, SQL, REST API design
Teams	OU Formula SAE

CONTENTS

02 • Paddle Shifters	· Designed, printed and fitted to my car	page 3
03 • Tolerance Stack-Up	· Machining and inspection at my SAGA internship	page 4
04 • Woodworking	· Handcrafted pens, built from scratch on the lathe	page 5

PROJECT 01

Stockwell

Software that saves small retail shops **time** and **money**. It schedules the staff and restocks the shelves. Built and shipped solo.

SAVES TIME · SCHEDULING

Staff availability goes in, a finished weekly schedule comes out. What took a manager hours of rearranging every week now takes a review and a click.

SAVES MONEY · RESTOCKING

It watches stock levels in real time and reorders from the vendor before anything runs out, so shelves stay full and nothing sells out at full price.

ENGINEERING HIGHLIGHTS

NEVER TRUST THE AI

The AI proposes a schedule; separate code verifies it. Double-bookings and untrained assignments get repaired, not published.

PROVEN ISOLATION

Many businesses, one server. A test battery has one try to reach another's data on every run. Every attempt must fail.

BUILT TO BE SWAPPED

Database, AI, email and imports each sit behind small interfaces, so any one can be replaced without touching the rest.

PROJECT 02

3D Printed Paddle Shifters

Extended paddle shifters for my Audi A7, designed from scratch to fit the factory mounts. Modelled, printed, test fitted, refined, then sanded and clear coated.

Original paddle mount.

Paddles after sanding and clear coat.

PROCESS

1 • Model. Surfaced the paddle profile in SolidWorks.

2 • Print. Orientation and supports set for strength.

3 • Final look. Both paddles fitted, circled.

WHAT MADE IT HARD

FIT BEFORE FORM

The mount had to grip the factory paddle exactly. I printed fit checks before committing to a full part, so the tolerance was proven early.

SURVIVED A TEXAS SUMMER

PLA starts softening near 140°F, and a parked car in 105°F sun runs past 130°F. The paddles have held their shape and fit with no warping.

FINISH IT PROPERLY

Sanded through grits and clear coated so the part reads as a factory interior piece instead of a printed one.

Tolerance Stack-Up on a Client Assembly

Two summers machining, measuring and troubleshooting parts for a client build. My main job was a run of aluminum brackets that had to pass inspection *and* actually go together in the finished assembly.

The assembly the machined parts had to fit into.

Checking a finished bracket against the print.

The part. Client drawing, revision E, held to ± 0.005 in.

Shop piece. Turned and engraved on the lathe.

WHAT I WORKED OUT

IN SPEC IS NOT THE SAME AS FITS

Parts could each pass their own dimensions and still refuse to go together. The problem lived in how the tolerances stacked at the interfaces, not in any one number.

MEASURE BEFORE YOU MACHINE MORE

I inspected parts against the drawing with calipers as they came off, so a drifting dimension got caught on one part instead of a whole batch.

THE CLIENT'S PRINT IS THE SPEC

It had to be exactly what was drawn and it had to work assembled. Anything I changed to make parts fit still had to land inside the drawing.

Woodworking: Handcrafted Pens

Pens built from scratch on the lathe. Raw blanks get drilled, sleeved with brass, turned to size, finished and press fit to hardware. An ongoing exercise in doing the same precise thing repeatably, by hand.

Finished pens across several kits and blank materials.

One production run, turned to match.

Where they start

Blanks are drilled and a brass tube is epoxied inside, then sorted by kit. That tube is the reference every later operation works from, so getting it straight decides whether the finished pen is square.

WHAT THE WORK DEMANDS

EVERY PIECE IS UNIQUE

No two blanks have the same grain, so no two pens finish the same. Reading the wood and orienting it before it ever hits the lathe is half the design.

PRESS FIT, NO FASTENERS

Components press into the tubes on an interference fit. Too loose and it spins, too tight and the blank splits. The ends have to be square and to length.

IDENTICAL WHERE IT COUNTS

The grain is always different, the geometry never is. Diameter, sanding sequence and finish stay the same on every piece so each one still fits its hardware.
